

Clearly, if the real-life situation is as both the actual course and this is a theoretical study and while it is possible to change irradiance and/or will process variations in PV module temperature, it is also possible to affect the conditions of an I-V variation as a result of the latter in order to keep the temperature of the PV module stable before and after the change in the PV module temperature measurement, the stable conditions of irradiance during an I-V curve measurement can influence the shape of the I-V curve.
